# Outline of Talk

---

- Fuel cells and the “hydrogen economy”
- Environmental benefits and challenges
- The role of carbon sequestration
- A potential path to sustainability

# Fuel Cells and the “Hydrogen Economy”

---

- Advanced fuel cells generating electricity from reactions of hydrogen and oxygen are intimately associated with the concept of a “hydrogen economy”

# Why the Interest in Hydrogen?

- **Hydrogen as a clean end-use fuel**  
(reducing emissions of conventional pollutants and greenhouse gases)
- **Hydrogen as a national security asset**  
(reducing oil imports and associated vulnerabilities)
- **Hydrogen for sustainable development**  
(replacing depleted fossil fuel resources over the next century and beyond)
- **Hydrogen as “manifest destiny”**

# Major Environmental Concerns Driving Interest in Fuel Cells and Hydrogen

## *Near-term Issues:*

- Air pollutants affecting human health
  - Transportation sector (CO, HC, NO<sub>x</sub>, Pb)
  - Other sectors (SO<sub>2</sub>, NO<sub>x</sub>, PM<sub>10</sub>, Hg)

## *Longer-term Issue:*

- Greenhouse gases affecting global climate
  - CO<sub>2</sub> emissions from fossil fuels
  - Other GHGs from human activities

# Hydrogen as a “Zero Emission” Fuel for Pollution Control

- Increasing stringency of automotive emission standards (esp. California ZEV requirements) helped promote substantial recent interest and investments in vehicles using H<sub>2</sub>-powered fuel cells
- A wide array of public and private RD&D programs on H<sub>2</sub>-powered vehicles (including SECA, FreedomCAR)
- *But many tough problems must be solved before fuel cells and H<sub>2</sub> can compete successfully with alternative transportation fuels and prime movers*

# Challenges of H<sub>2</sub> for Transportation

- Technology for H<sub>2</sub>-powered Vehicles
  - Performance
  - Cost
  - Safety
  - Public Acceptance
- Infrastructure for H<sub>2</sub>-powered Vehicles
  - Technology
  - Cost
  - Safety
  - Timing
  - Who will pay for it?

# The Long-Term Goal of Carbon-Free Energy

- 1992 U.N. Framework Convention on Climate Change called for “stabilization of greenhouse gas concentrations in the atmospheric at a level that would prevent dangerous anthropogenic interference with the climate system”
- This implies a long-term need to drastically reduce CO<sub>2</sub> emissions, no matter what stabilization target is selected!
- *This will require major long-term changes in our energy system, with electricity and hydrogen playing critical roles as carbon-free energy carriers*

# Percentage of U.S. CO<sub>2</sub> Emissions by Energy Source and End-Use Sector

(Based on total CO<sub>2</sub> emissions of 5727 million metric tons in 2000)

Energy Source	End-Use Sectors				
	Residential	Comm'l	Industry	Transport	Total
Petroleum	1.8	0.9	5.6	32.2	<b>40.4</b>
Natural Gas	4.7	3.2	6.7	0.7	15.2
Coal	0.1	0.1	2.1	-	3.2
Electricity	13.5	13.0	15.4	0.1	<b>41.9</b>
<b>Total</b>	<b>20.1</b>	<b>17.1</b>	<b>29.8</b>	<b>33.0</b>	100.0

# But Is H<sub>2</sub> Really Carbon-Free?

- Zero CO<sub>2</sub> emissions at the tailpipe or stack does not necessarily mean carbon-free energy
- Must look at how hydrogen is produced, and evaluate all emissions over the full life cycle (fuel cycle)

# The Production of Hydrogen

- *The Dream Scenario:* H<sub>2</sub> produced from electrolysis of water using electricity produced from clean renewable energy (solar, wind):

- *The Current Reality:* Most H<sub>2</sub> is made by steam reforming of natural gas:

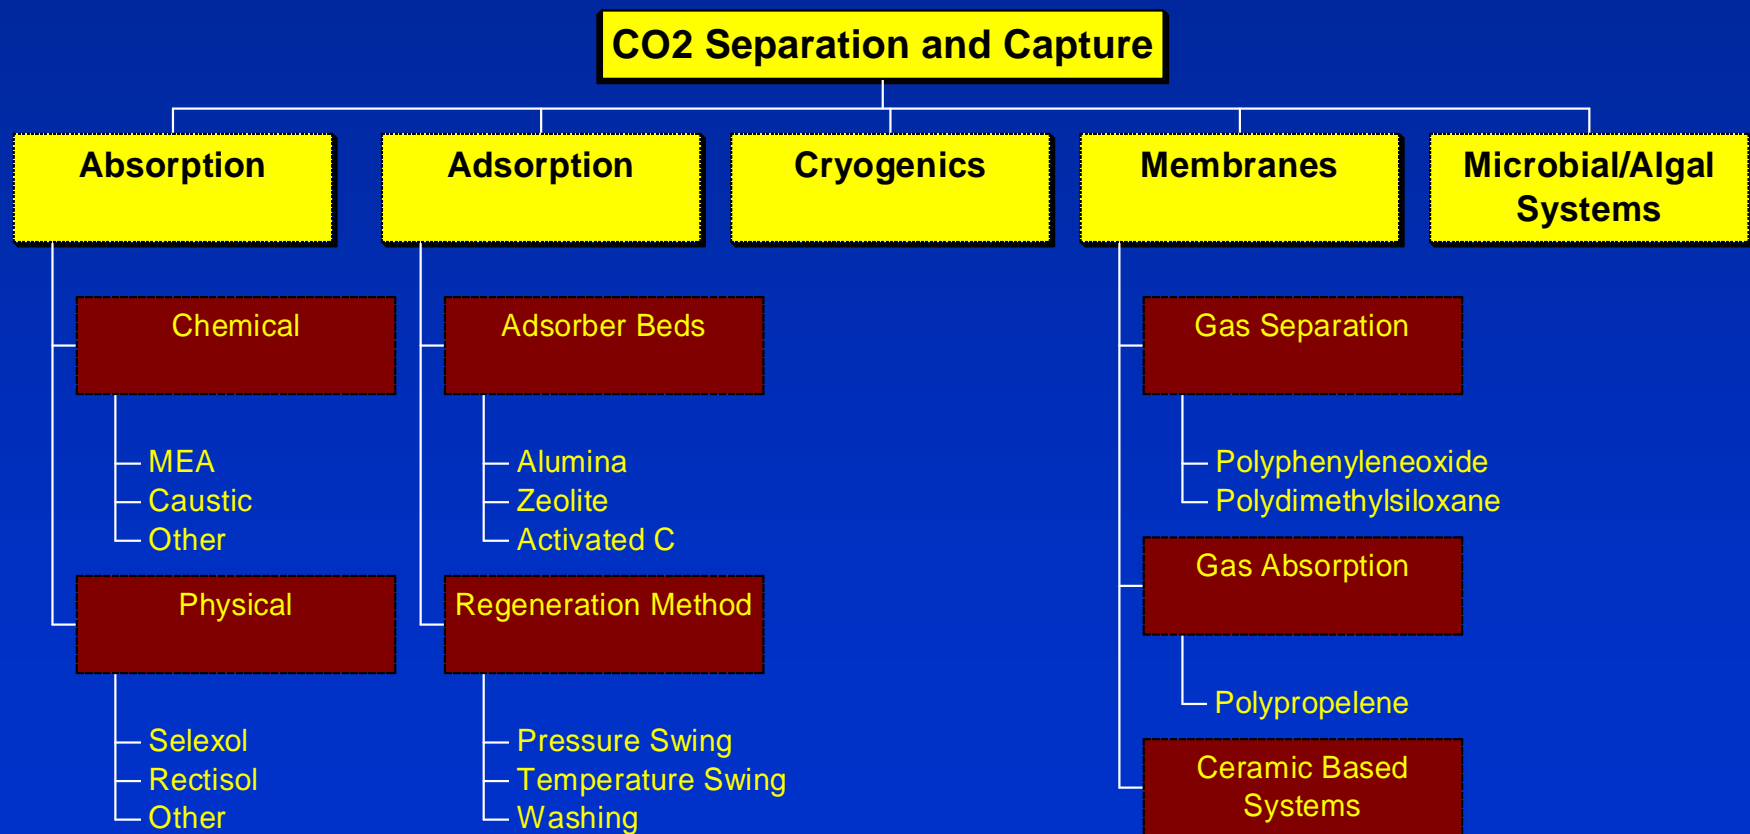

Result: 5.5 tons CO<sub>2</sub> emitted per ton H<sub>2</sub> produced

# Enter Carbon Sequestration

- Until recently, the term “carbon sequestration” referred to the natural uptake of CO<sub>2</sub> by trees and other biomass (terrestrial sequestration)
- Today this term also includes the capture and storage of CO<sub>2</sub> from power plants and other industrial processes
- Carbon capture and storage (CCS) technology potentially can allow fossil fuels to be used with little or no emissions of CO<sub>2</sub> to the atmosphere

# Many Ways to Capture CO<sub>2</sub>

# Potential Options for CO<sub>2</sub> Storage

- Geologic Sequestration
  - Depleted oil and gas wells
  - Unmineable coal seams
  - Deep saline reservoirs
- Terrestrial Sequestration
- Mineralization
- Ocean Sequestration
- Other Novel Concepts

# Carbon Storage Capacity

<b>Storage Option</b>	<b>Worldwide Capacity (Order of Magnitude)</b>
Deep Reservoirs	100s – 1000s GtC
Depleted Oil and Gas	100s GtC
Coal Seams	10s – 100s GtC
Terrestrial	10s GtC

# Another View: Carbon-Free Hydrogen from Coal

# How Far-Fetched Is This?

*Many of the pieces already exist commercially:*

- Gasification of coal and other feedstocks is a commercial technology used extensively in world industry (including power generation applications)
- Hydrogen production today is a well-developed, commercially-proven industry
- CO<sub>2</sub> capture technology also is used commercially today in a variety of process industries
- CO<sub>2</sub> injection and storage in geologic formations has been widely used for enhanced oil recovery and disposal of acid gases; several large-scale sequestration projects are now underway

# Carbon Sequestration R&D

- Goals are to develop and demonstrate improved, lower-cost and effective methods of CO<sub>2</sub> capture and storage
- Major R&D programs underway worldwide, led by both government and industry, e.g.,:
  - U.S. Department of Energy
  - International Energy Agency
  - CO<sub>2</sub> Capture Project
  - Canadian Clean Power Consortium
  - ... and many others

# Many Issues Yet to be Resolved

- Acceptance of carbon capture and storage as a viable method of CO<sub>2</sub> abatement
- The success of R&D efforts in lowering the costs of carbon capture, fuel cells, and other advanced power generation systems
- Development of infrastructure needed to support a hydrogen-based energy system
- Timing, magnitude and nature of future emission constraints for greenhouse gases

# Conclusions

- A future “hydrogen economy” is by no means assured; a host of technical, economic and political challenges remain to be overcome before this could happen
- BUT, if societal concerns about climate change and sustainability become increasingly important, the use of hydrogen could grow in the decades ahead
- In this picture, fuel cells — together with carbon sequestration and gasification technology — could play a major role in plowing a “zero emissions” path to a sustainable future (ultimately based on cost-effective renewable energy technology)
