12 McQueen *et al.* [1] continue to argue against interactive 52 selective adaptation (the unambiguous condition in Ref.  
13 processes in speech perception, but we suggest that their 53 [6]), as predicted by interactive processing.  
14 arguments are unconvincing. Theoretical and empirical 54 In sum, McQueen *et al.* [1] have provided neither a  
15 arguments support the interactive account. Concerning 55 theoretical basis nor a sufficient argument to bring into  
16 their theoretical points, a rational analysis is consistent 56 doubt the evidence that supports interactive processes in  
17 with interactive models because they can produce optimal 57 speech perception. Lexically guided learning is not a  
18 information integration [2]. We argue that interactive, 58 special case for which feedback must be introduced; it is  
19 rather than feedforward, processing is the algorithm that 59 just one of many benefits of interactive processing.  
20 the brain uses to accomplish optimal information 60  
21 integration. Interactive processing provides a more 61  
22 parsimonious algorithm than the feedforward approach of 62  
23 McQueen *et al.*, which requires an additional decision level 63  
24 and a specialized feedback mechanism that affects 64  
25 learning but not processing. 65

26 We suggest that the empirical arguments offered by 66  
27 McQueen *et al.* are also unconvincing. The failure to find 67  
28 lexically mediated compensation for coarticulation in Ref. 68  
29 [3] is not problematic; the lexically mediated effect will 69  
30 necessarily be smaller than the effect that is produced by 70  
31 an unambiguous phoneme (Figure 2 in Ref. [4]) and might 71  
32 [Au: 'may' is ambiguous and can imply 'can', 'could' or 72  
33 'might'. Is 'might' OK here?] be too small to be detected 73  
34 reliably. Furthermore, one failure to replicate cannot 74  
35 outweigh three independent successful replications that 75  
36 were based on 16 different lexical contexts (reviewed in  
37 Ref. [4]). Regarding the 'higher-order transitional  
38 probability' argument of McQueen *et al.*, there is no  
39 definition of 'higher-order transitional probability' that  
40 can account for the full set of data [5].

41 Perceptual learning cannot explain lexically induced  
42 selective adaptation as neatly as McQueen *et al.* claim.  
43 They cite audiovisual recalibration data from the  
44 ambiguous condition in Ref. [6] that showed learning  
45 followed by adaptation-driven unlearning. However, the  
46 lexically mediated selective-adaptation data (Figure 3 in  
47 Ref. [6]) correspond more closely to the unambiguous  
48 condition (Figure 1 in Ref. [6]), showing selective  
49 adaptation relative to baseline. This correspondence  
50 suggests that lexically mediated selective adaptation  
51 operates in the same way as perceptually mediated
