Abstract

The Hamerschlag Hall green roof at Carnegie Mellon University, Pittsburgh, Pennsylvania, was constructed in 2005, and has been monitored to evaluate its performance in reducing storm water runoff and extending the runoff duration. Green roofs can reduce the amount and rate of storm water runoff by covering the impervious roof with porous soils that can retain water and plants that evapotranspire the stored water. Storm water runoff from two hydraulically isolated areas on the Hamerschlag Hall green roofs have been monitored semi-continuously since 2008, as a control area of similar size on the adjacent flat roof which is not a green roof. From analysis of data for storms from 2009-2011, it was found that the green roof reduces the runoff volume by up to 100% compared to the control roof for small rainfall events of 0.1 inch or less. A reduction of at least 45% was found for rainfall storms between 0.1 and 0.6 inch. For events less than 0.6 inch, the reduction in the runoff peak flow rate from the green roof compared to the control roof was between 80%-100%. Runoff flow duration is extended for the green roof by at least several hours compared to the control roof. Insufficient data were obtained for large rainfall storms(rainfall depth over 1 inch), so the performance of the Hamerschlag Hall green roof is yet not to be determined under heavy rain.

Key word: storm water runoff retention, green roofs, peak flow, duration

1. Introduction

Cities which have a combined sewer systems, like Pittsburgh, Pennsylvania, often have the sewer overflow discharges which send the diluted sewage into streams. Technologies such as green roofs that can reduce sewer overflows are of interest in areas with frequent sewage overflows.

Green roofs are engineered roof systems incorporating porous soil, or a synthetic growing medium and drought-tolerant plants, installed over a conventional roof with a waterproofing membrane. The environmental advantages of green roofs are:(1) reduced heating and cooling loads on the building space beneath the green roof due to add insulation provided by the green roof; (2) increased life span for the roof due to protection from solar radiation and other weathering;(3) reduced stormwater runoff volume and runoff peak flow rate and extension of the runoff duration.

There are two kinds of green roofs, intensive and extensive (Miller, 2005). Intensive green roofs are characterized by thick soil layers (8 in-4 ft), heavy weight and elaborate planting, which requires considerable maintenance. Extensive green roofs are much lighter in weight with soil depth ranging from 3-7inches (Worden, et al,2005). Due to the relatively thin soil layers and the low maintenance requirement, plants are typically low growing ground cover that are tolerant of sunlight and drought.

The Hamerschlag Hall green roof at Carnegie Mellon University, installed in 2005, was designed as an aesthetic environment, and also to provide improved thermal insulation and storm water

retention characteristics. In addition, it was designed with monitoring systems to enable assessment of energy and storm water performance.

The objectives of this research study were to (1) investigate the effect of Hamerschlag Hall green roof on selected storm water runoff and rainfall quantity characteristics during 2009-2011; (2) evaluate quantitatively the overall performance of Hamerschlag Hall green roof for retaining stormwater, extending the duration of the flow, and reducing the peak runoff flow rate; and (3) enable prediction of the future water retention and runoff reduction performance of the green roof.

2. Hamerschlag Hall Green Roof

The Hamerschlag Hall green roof at Carnegie Mellon University is a 4500 ft² extensive green roof. The green roof was installed on top of a conventional modified bitumen flat roof. The Hamerschlag Hall green roof is shown in plan view in Figure 2.1. The adjacent control roof, also shown in Figure 2.1, has no soil or vegetation. The Hamerschlag Hall green roof has two water monitoring areas. Each monitoring area is hydraulically isolated and has one trapezoidal flume to measure outflow of water. The roof has five drains as indicated on Figure 2.1. The green roof water monitoring areas drain to two of the five drains. The other three roof drains accommodate drainage onto the roof from another roof above it, as well as runoff from the non-monitoring areas of the green roof. The two monitoring areas are hydraulically isolated from influence of the

upper roof run-on by means of a separate membrane under each of the areas.

A cross section of the Hamerschlag Hall green roof is shown in Figure 2.2. In the water monitoring areas, the thickness of synthetic soil growing medium is approximately 10 cm as indicated in Figure 2.2. In other areas of the roof, the synthetic soil is somewhat thicker.

Each monitoring area covers approximately 650 square feet of the green roof surface, making the total monitored area 1300 square feet, or about 30% of the total area of the green roof. The dimensions of each green roof water monitoring area are shown in Figure 2.3

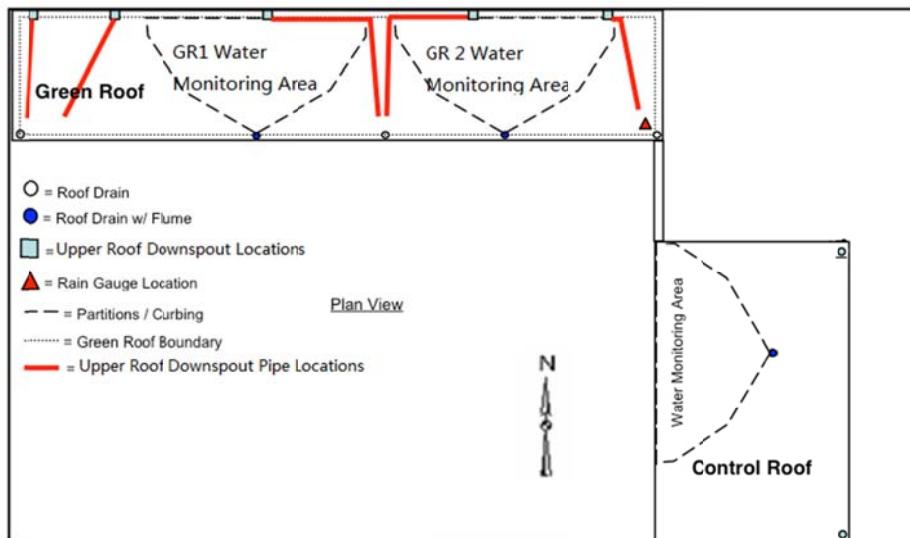

Figure 2.1 Plan view of the Hamerschlag Hall Green Roof and adjacent control roof with monitoring area locations. (Source: modified from Anumol et al., 2010)

3. Water Runoff Monitoring system

To measure the performance of the Hamerschlag Hall green roof on managing the storm runoff, there is flow monitoring equipment installed on both the green roofs and the control roof. A LabView and National Instruments Fieldpoint Data Logging system and a PC computer with LabView data acquisition software are also in place collect the runoff quantity data and store data in the computer.

3.1. Flumes

Flow from each water monitoring area on Hamerschlag Hall green roof is measured using 0-30 gpm trapezoidal open channel flumes(Plastifab,60° V trapezoidal flume, Tualatin, Oregon). The stormwater falling on the green roofs and control roof monitoring areas can only leave the monitoring areas through these flumes, which enables monitoring of runoff flow rate.

The trapezoidal flumes were factory calibrated and were provided with a factory calibrated empirical flume equation. This converts the height of water in the flume to the corresponding flow rate (Anumol et al., 2010).

$$Q = 1.55 \times 60 \times \left(\frac{H}{12} \right)^{2.58} \quad (3-1)$$

where H is the water height in inches, and Q is the volumetric flow rate in cfs. A photograph of the flume is shown in Figure 3.1

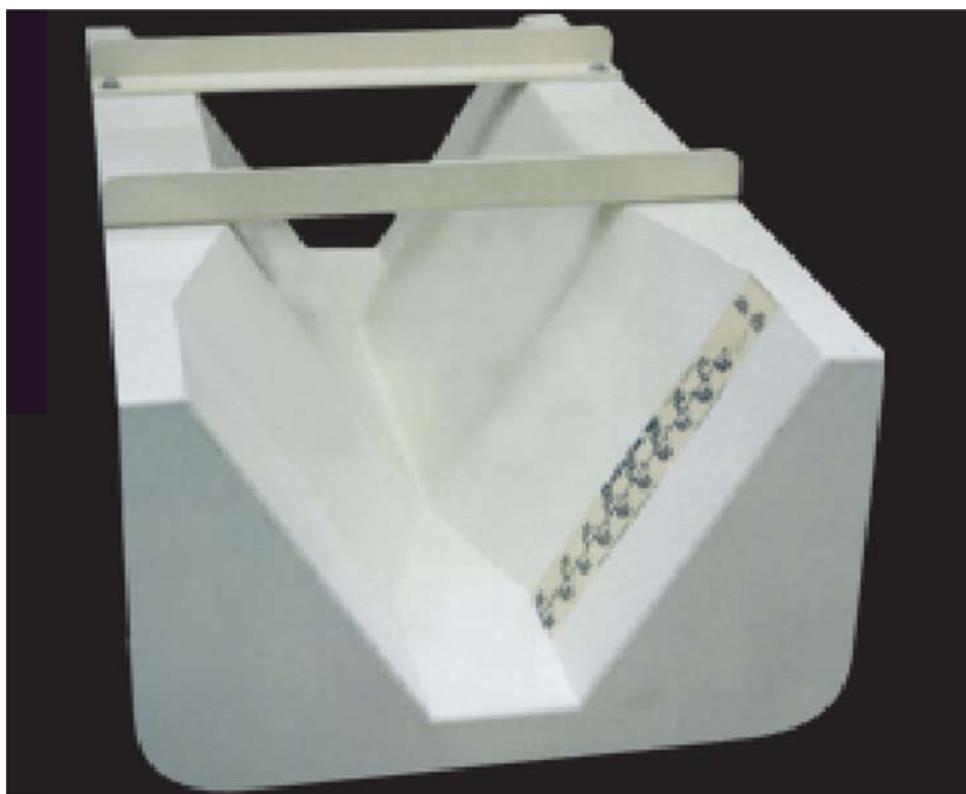

Figure 3.1 Trapezoidal flume, measures 0-30 gpm(Plastifab,60° V)

Source: <http://www.plasti-fab.com/wastewater-products/trapezoidal-flumes>

3.2. Ultrasonic Sensors

The water height in the trapezoidal flumes is measured semi-continuously with the use of ultrasonic sensors (Stevens Water Monitoring System, Inc, Portland, OR). The water level is sensed every minute, and the ultrasonic signals are converted to electric current (mA) pulses which are transmitted to the National Instruments data logger. A computer with Labview software is used to record the data. With defined calibration equations in this system, the electronic sensor signals can be converted into water height and flow rate automatically (Anumol et al., 2010).

3.3. Flume Calibration

The ultrasonic sensors used to measure water height in the flumes for the two green roofs and control roof are calibrated with an 8 oz. paper coffee cup, which is marked with different water weight level in advance. Water is poured into the cup filling it to the various specified levels and the ultrasonic sensor transmits a corresponding output in milliamperes to the data logger and LabView system. A point to note is that the water height is a measured distance from the horizontal plane on which the cup is placed, as shown in Figure- 3.2 (Anumol et al., 2010).

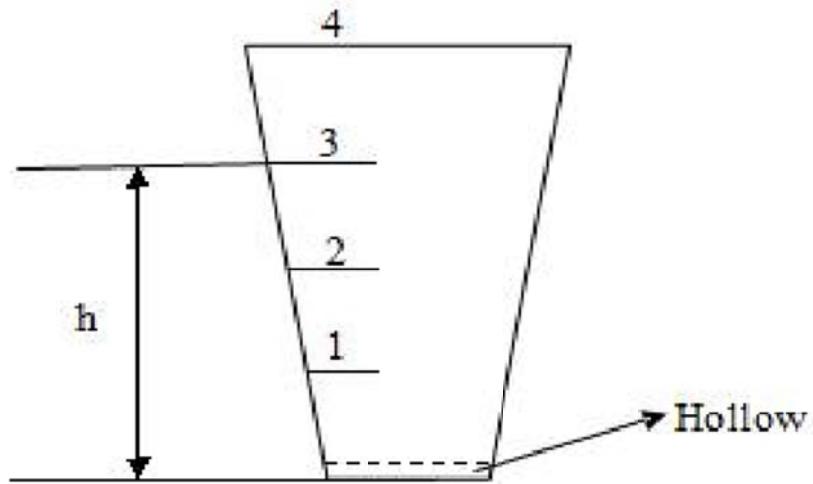

Figure 3.2 Schematic illustration of an 8 oz paper calibration cup and its placement on the flat bottom of the trapezoidal flume (Anumol et al., 2010).

Table 3.1 Cup scale depth and pouring water procedure for flume calibration (Anumol et al., 2010)

cup water level	Height H(inch)	Note
0	0	Do not put cup in the flume when calibrating for zero level
1	1	Pour water into the cup to the level 1
2	1.8	Pour water into the cup to the level 2
3	2.6	Pour water into the cup to the level 3
4	3.7	Pour water into the cup to the level full

The calibration procedure is repeated three times, with the outputted current and the corresponding water level recorded each time; water heights are converted into flow rates with Equation (3-1). The data are then analyzed with Excel to obtain a linear equation relating the water height with the electrical current. The new calibration equation is entered into the

Labview system.

3.4. Rainfall Monitoring

When monitoring green roofs for stormwater runoff it is important to know the duration and intensity of each storm event. Rain gauges typically are used to measure the amount of rainfall over a particular period of time.

There are two approaches available to monitor rainfall received by the Hamerschlag Hall green roofs: rainfall measurement with a tipping bucket rain gauge on the green roofs or runoff from the adjacent control roof. The tipping bucket rain gauge installed on the Hamerschlag Hall green roof is shown in Figure 3.3. The tipping bucket mechanism is located within the cylindrical protective shroud located on the upper part of the tripod. The rain gauge is a model RG200 6" rain gauge (Global Water, Gold River, CA). It is used to monitor rainfall amounts continuously (Anumol et al., 2010).

Figure 3.3 Tripod with Tipping Bucket Rain Gauge on the Hamerschlag Hall green roof (Anumol et al., 2010).

3.5. Data Acquisition System

The monitoring equipment on the roofs is connected to a National Instruments data logger, which is in turn connected to a computer. The water flume data are collected using the National Instruments program, LabView, and the rain gauge is controlled through the program “Global Logger II.”

Rain gauge data were used to measure the start time of the storm event, storm duration, and the rainfall volume. Roof runoff flume data measured by LabView system gave the runoff duration,

and runoff volume on the green roof and the adjacent control roof. Combining these two types of data together gives the overall performance of the green roof on runoff volume reduction and peak flow rate reduction.

3.5.1 Collecting the Water Flume Data

The Labview system should be open and running at all times. If the system is not running, no data will be collected. The Labview window is shown in Figure 3.4. The Labview system will save a new file for each day in the specific folder in the PC computer.

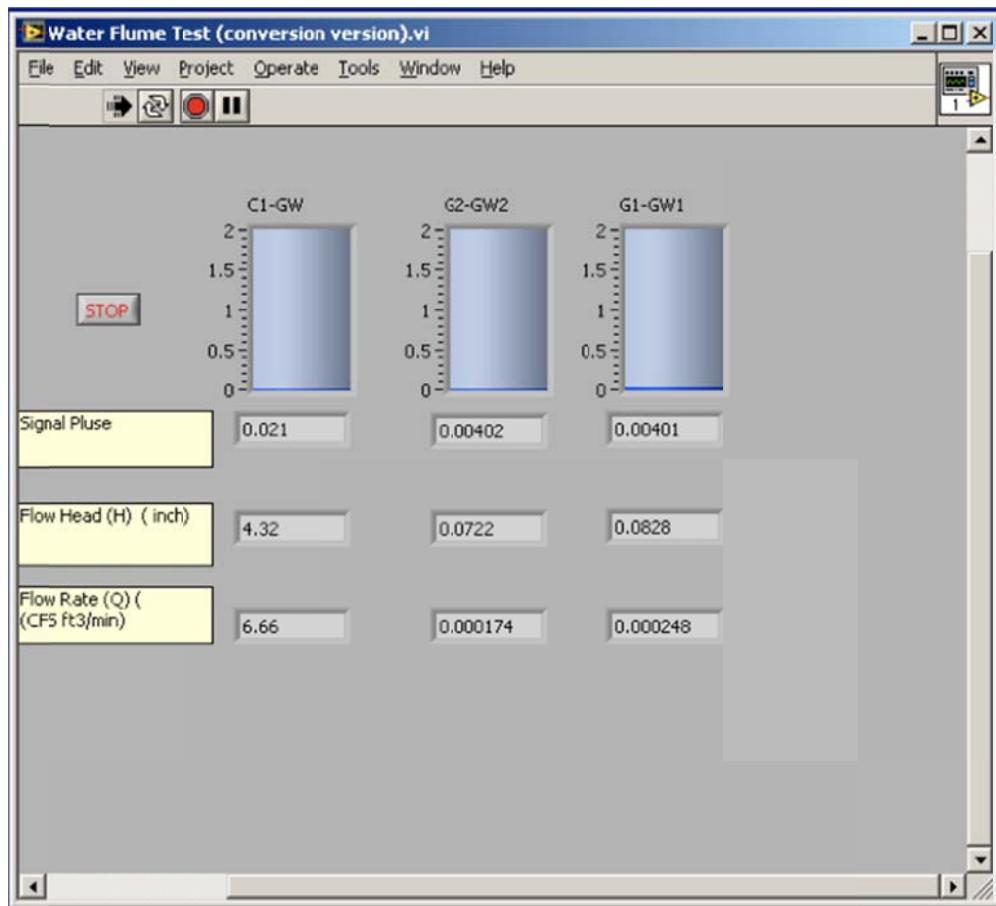

Figure 3.4 Water Flume Test (conversion version).vi running in LabView

3.5.2 Collecting the Rain Gauge Data

The data logger system doesn't need to operate at all times. It should be open whenever the rain gauge data are required. Figure 3.5 shows the interface of the Global Logger system. Connecting the “get history” icon, the system will upload the data automatically. It should be noted that the Global Logger can only store two months of rain gauge data, or it will overwrite the previous data. Any data not downloaded from Global Logger during that two month will be lost.

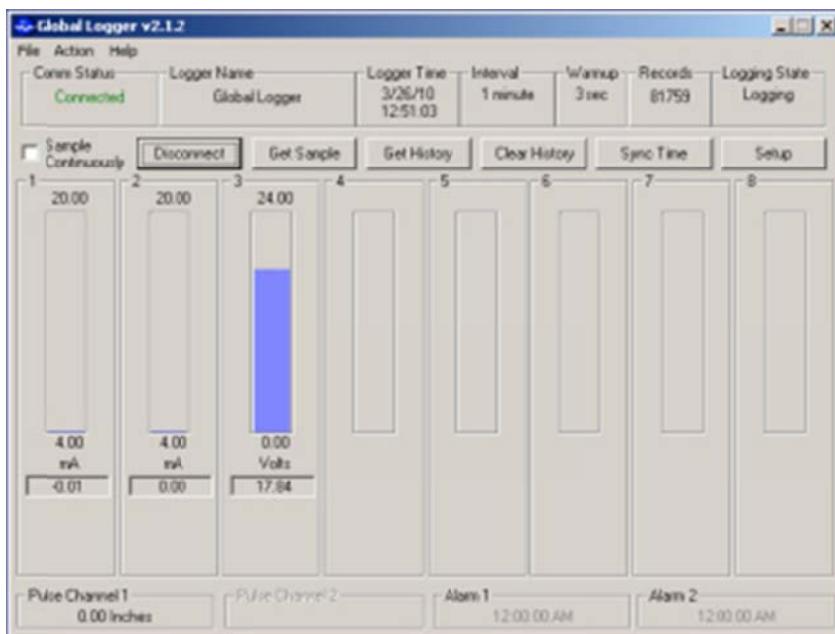

Figure 3.5 Software interface for Rain gauge monitoring program, Global Logger

4. Methods of Storm Analysis and Green Roof Performance Analysis

Analysis of the performance of the green roof is done on a storm by storm basis. A series of calculations for each storm event needs to be performed. The period of Hamerschlag Hall green roof performance analyzed in this report is from January 1, 2009 to April, 30, 2011.

4.1. Individual Storm Definition

The first step in analysis of a storm is defining a storm event. A storm must meet three criteria to be defined as an individual storm event. Table 4.1 summarizes the criterion for definition of a storm. The first criterion is the Minimum Inter-event Time (MINT). The MINT is the length of time required to be met or exceeded before and after each storm event. (Dunkerley, 2008). MINT values may range from 3 minutes to 24 hours. For the Hamerschlag Hall green roof project, MINT of 6 hours was chosen (Manfroi et al., 2004).

The second criterion is the duration of the storm event itself. For the Hamerschlag Hall green roof, a value of 30 minutes was adopted as per recommendations in the literature (Fornis, et al. 2005)

The final criterion for definition of a storm is the depth of rainfall. For the Hamerschlag Hall green roof, the minimum amount of rain that the rain gauge should register to be considered a storm event is 0.5 mm or 0.02inch.

Table 4.1 Criteria for Definition of an individual Storm

No rain for 6 hours before or after the storm event
The duration of the storm event must be at least 30 minutes
The total rainfall must be at least 0.02 inch

4.2 Measures of Green Roof Performance

After determining the storm event, the start time, end time, time of peak flow and the peak flow can be obtained directly from the hydrograph. Figure 4.1 shows visually where the characteristics are located on the hydrograph.

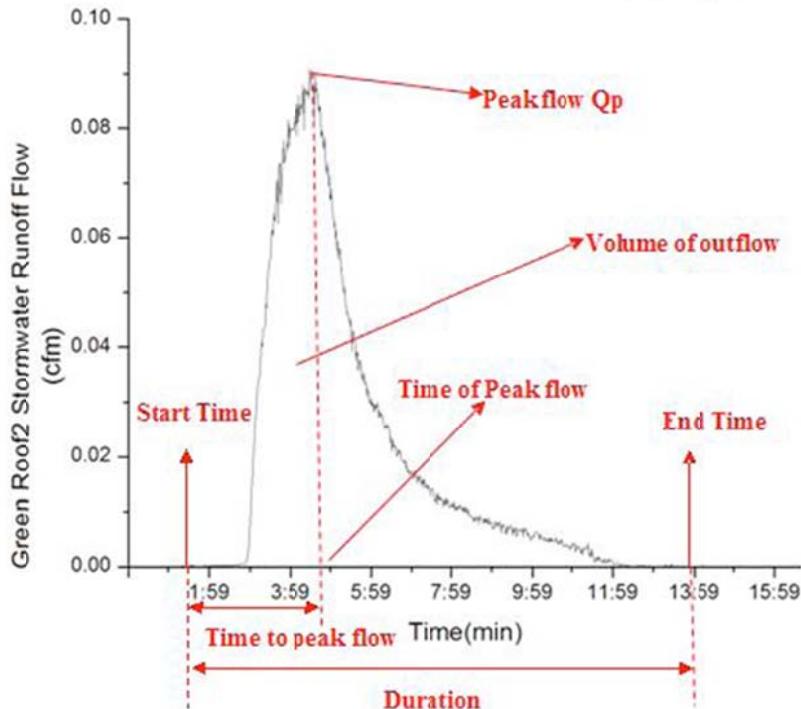

Figure 4.1 Example Hydrograph from Hamerschlag Hall Green Roof (Anumol et al., 2010).

The storm characteristics taken from the hydrograph can then be calculated to provide other useful metrics, which can be used to compare the performance of the green roofs and the control roof for different storms. Table 4.2 shows these metrics and how they be defined. The metrics were developed by Anumol et al., (2010).

Table 4.2 Storm metrics definition and calculated equations

Metric	Definition	Equation
Duration	Total length of the storm	Duration=End time-Start time
Time to Peak	The time it takes for the flow off the roof to reach its peak	Time to Peak=Time of Peak-Start time
Volume Reduction	The ratio of the volume retained by the green roof to the total volume of runoff from the control roof	$V_{\text{Reduction}} = \frac{V_{\text{control roof runoff}} - V_{\text{green roof runoff}}}{V_{\text{control roof runoff}}}$
Q _p Reduction	The ratio of the absolute reduction of the peak flow to the peak flow on the control roof	$Q_p \text{ Reduction} = \frac{Q_{P,CR} - Q_{P,GR}}{Q_{P,CR}}$
Q _p Ratio	The ratio of peak runoff rate on the Green Roof to the peak runoff rate the control roof	$Q_p \text{ Ratio} = \frac{Q_{P,GR}}{Q_{P,CR}}$
Time to Peak Extension(TPE)	Ratio of the difference in time to peak between the green roof and control roof to the time to peak on the control roof.	$TPE = \frac{t_{P,GR} - t_{P,CR}}{t_{P,CR}}$
Relative Duration(RD)	The ratio of duration of green roof runoff, DGR and control roof runoff, DCR	$RD = \frac{D_{GR}}{D_{CR}}$
Runoff Volume Ratio	Ratio of total runoff on the green roof to the runoff on the control roof	$\text{Runoff Volume Ratio} = \frac{V_{\text{green roof runoff}}}{V_{\text{control roof runoff}}}$

5. Results and Discussion

A total of 51 individual storm events during the observed period from January 2009 to April 2011

were identified by analysis of the rain gauge data. Of the total 51 events, 12 events precipitated

between 0.01 inch to 0.1 inch, and there were 34 rainfall events with between 0.1 inch to 0.6

inch and only 5 events with more than 0.6 inch of precipitation. Some of the 51 storm events included days when snow occurred in winter.

5.1 Typical storm analysis

Two typical storms are analyzed below to demonstrate the performance of Hamerschlag Hall green roof. The first storm occurred on 11/27/2009, when 0.091 inch of rain landed on the roofs in approximately 7 hours (0.014 in/hr average intensity). The second storm, on 12/8/2009-12/9/2009, was much larger than the first one, yielding 1.43 inch of rain in about 10 hours(0.13 in/hr average intensity). The second storm was the heaviest one of those monitored on the roof during 2009. Figures 5.1 and 5.2 shows hydrographs for these two storms.

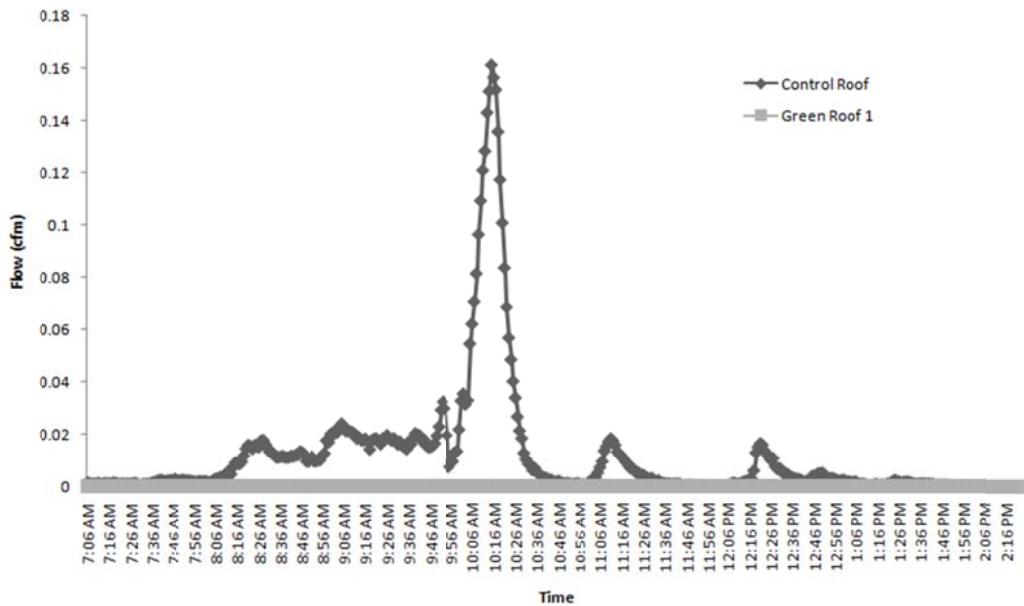

Figure 5.1 Runoff flow rates vs. time for the control roof and Green Roof 1 for the 11/27/2009 storm

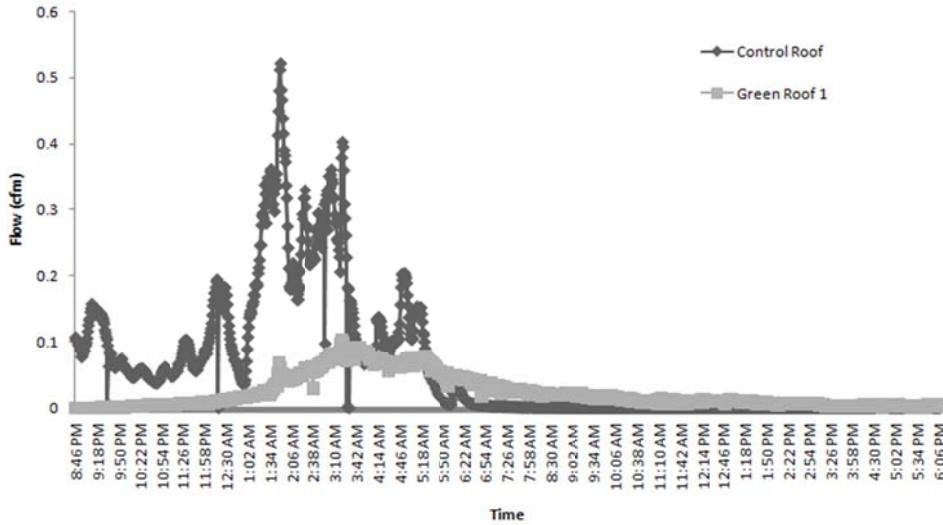

Figure 5.2 Runoff flow rates vs. time for the control roof and Green Roof 1 for the 12/8/2009-12/9/2009 storm.

The results in Figure 5.1 show that the Green Roof 1 significantly reduced the runoff volume for the low intensity storm of 11/27/2009 with a volume reduction of 100%. In Figure 5.2, the volume reduction for the higher intensity storm of 12/08/2009-12/09/2009 storm was of 62.7%.

The green roof also attenuated the maximum flow rate for each storm. For the 11/27/2009 storm, the maximum flow rate of the green roof was 100% lower than the control. For the 12/08-09/2009 storm, which had higher rainfall intensity, the maximum flow rate of the green roof was 80.4% lower than the control roof.

Figure 5.2 shows the delay of the runoff peak flow rate and extension of runoff duration for the 12/8/2009-12/9/2009 storm. There was a delay between the time rainfall started and runoff began to flow on the green roofs. Because of the lack of growing medium and plants, the control roof consistently exhibited runoff earlier. Figure 5.2 shows that the control roof produced runoff

approximately one hour before the green roof did. It should be noted that the rainfall start time as determined from the rain gauge should be earlier than the time the control roof produces runoff, and the start time on Green Roof 1 should lag behind the control roof. However the start time was considered always the same for these two roofs for simplicity in this project.

Generally, runoff continues to flow from the green roof after the rainfall stops and the control roof stops producing runoff. This delay was because the water entering the green roof must filter through the soil, drainage layer and filter membrane before it exits the roof and drains as runoff. During the 12/08-09/2009 storm, the runoff flow from Green Roof 1 was 3.7 hours longer than the runoff flow from the control roof.

5.2 2009-2011 Data Analysis

Tables 5-1, 5.2, 5.3 show all individual storm events identified form data obtained in 2009,2010, and 2011.

Note that monitoring was not continuous and that not all storm events each year were monitored.

Data shown for the storm events include storm duration, control roof discharge duration, rainfall volume and Green Roof 1 runoff volume reduction, peak flow rate reduction, and runoff duration extension being provided. Comprehensive data can be found in Appendixes A,B, and C. It should be noted that due to the equipment failure and maintenance shortage, the water flume data and rain gauge data from May-August were lost during 2009-2010.

Note: [a]: Storm Duration= Storm End Time –Storm Start Time

[b]: CR Discharge Duration= CR Runoff Start Time-CR Runoff End time

[c]: Rainfall Volume measured by Rain gauge Data

[d]: Rainfall Depth= (Rainfall Volume)/Monitoring Area(650ft²)

[e]:Average Rainfall Intensity = $\frac{\text{Rainfall Depth}}{\text{Storm Duration}}$

[f]: Runoff Volume Reduction = $\frac{V_{\text{CR,Runoff}} - V_{\text{GR,Runoff}}}{V_{\text{CR,Runoff}}}$

[g]: Q_P Reduction = $\frac{Q_{P,\text{CR}} - Q_{P,\text{GR}}}{Q_{P,\text{CR}}}$

[h]: Duration Extension = $\frac{D_{\text{GR}} - D_{\text{CR}}}{D_{\text{CR}}}$

Storm Number with “*” at front in 2010 means using Three Rivers Wet Weather data due to rain gauge data missing.

Table 5.1 shows that during 2009, there were 2 storm events which were between 0.01 inch-0.1

inch, 16 events between 0.1 inch-0.6 inch, and only 1 events are over 0.6 inch. The biggest

rainfall event observed was 1.37 inch. The Hamerschlag Hall green roof performed well for in retaining runoff for the 0.01inch-0.1 inch storms, it reduced 100% of storm water runoff; provided 100% peak flow rate reduction. However its performance in retaining runoff was reduced for bigger storms, Green Roof 1 showed about 55.4%-100% runoff volume reduction and fairly stable peak flow reduction rate, between 72.1%-100% for storm greater than 0.1 inch. It is worth pointing out that due to the definition of the duration extension, there is “-1” value of duration extension when the green roof retains all the storm water runoff.

Table 5.2 shows that during 2010 there were 10 storm events whose storm depth was between 0.01 inch and 0.1 inch, 12 events between 0.1 inch-0.6 inch, and only 3 out of 24 rainfall events are over 0.6 inch. For the low rainfall amounts, the green roof still showed good performance for runoff volume reduction and peak flow reduction, as it was able to reduce 100% of storm water runoff and peak flow rate. In the middle range of rainfall (0.1 inch-0.6 inch), the runoff volume reduction was 48.9%-94.5%, and the peak flow rate was attenuated by 29.8%-97.3%.

Table 5.3 and 5.4 list 7 storm events for the first four months of 2011, with only 1 of 7 storms over 0.6 inch due to the relative short monitoring period in 2011, 2 storms between 0.01 and 0.1 inch, and 4 storms between 0.1-0.6 inch. The green roof, not surprisingly, retained almost 100% storm runoff discharge for 0.01-0.1 inch precipitation events. In addition, when the precipitation was between 0.1-0.6 inch, the green roof still provided over 90% runoff volume reduction and peak flow reduction. On the other hand, when the rain was over 0.6 inch, the green roof couldn’t retain water and reduce peak flow in a more stable way.

5.3 Factors affecting Green Roof Performance

5.3.1. Rainfall amount

A total of 51 rainfall events during 2009-2011 were evaluated. Complete information is available in the appendices. For the 2009-2011 storms, there was a total of 15.32 inches of recorded precipitation, and there was a corresponding value of 13.14 inches (with a standard deviation of 0.46 inch) of control roof runoff compared to a value of 4.2 inch (with a standard deviation of 0.3 inch) of Green Roof 1 runoff. The green roof retained 72.6% of total incident precipitation, while the control roof retained 14% of the precipitation.

The water retention and peak flow reduction varied from one precipitation event to another. The runoff volume reduction on Green Roof 1 of the storms observed during 2009-2011 is plotted in Figure 5.3. From the figure, it clearly shows that there were many 100% runoff volume reduction storms during 2009-2011, when the control roof was producing runoff, while Green Roof 1 produced no runoff. There were 16 rainfall events during the observed period with no runoff on Green Roof 1, which indicates the Hamerschlag Hall green roof performed relatively well on water retention when the rainfall depth was less than 0.6 inch. Likewise, Figure 5.3 also suggests that the performance of the Green Roof 1 was similar at the same cumulative rainfall point in different storms.

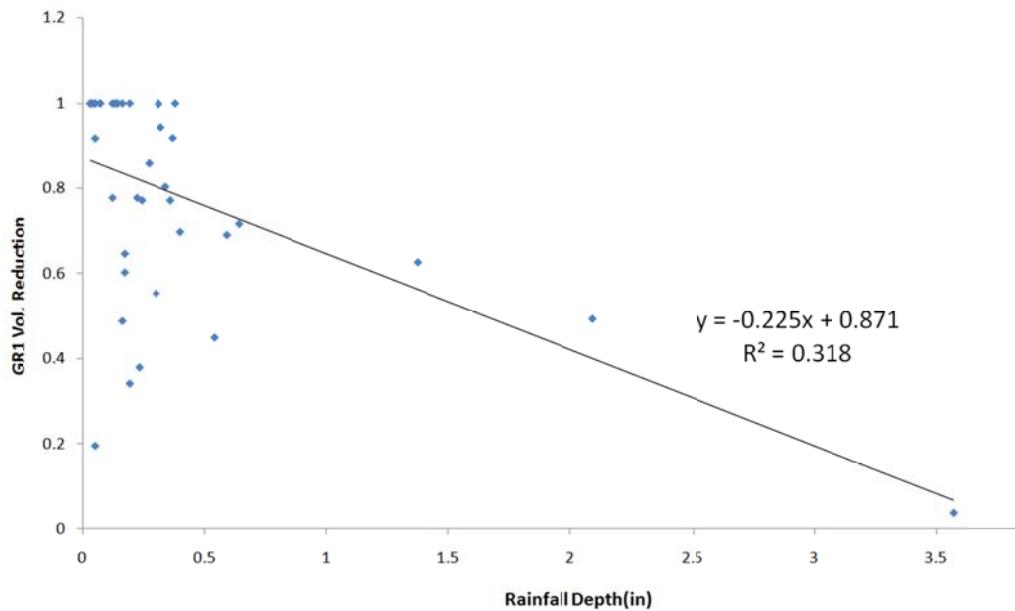

Figure 5.3 Runoff volume reduction on Green Roof 1 versus rainfall depth for all storms observed during 2009-2011 with trend line and linear regression equation

The Q_p reduction on Green Roof 1 of the storms observed during 2009-2011 is plotted in Figure 5.4. Some observations can be made by looking at the summary graphs showing results from all storms during the observed period. First, in Figure 5.4, the rainfall depth has an effect on the peak flow reduction of the green roof. Smaller rainfall events reduced the peak flow by a greater amount than the larger ones. This is because the green roof has its own limitation in water holding capacity. Secondly, the graph shows the range of rainfall depth that the green roof can handle with 100% retention and 100% peak flow reduction for storms with rainfall amounts less than 0.2 inch.

While it is reasonable to expect the rainfall intensity to be related to the peak flow reduction, a strong relationship between these two parameters was not observed, as shown in Figures 5.5 and 5.6.

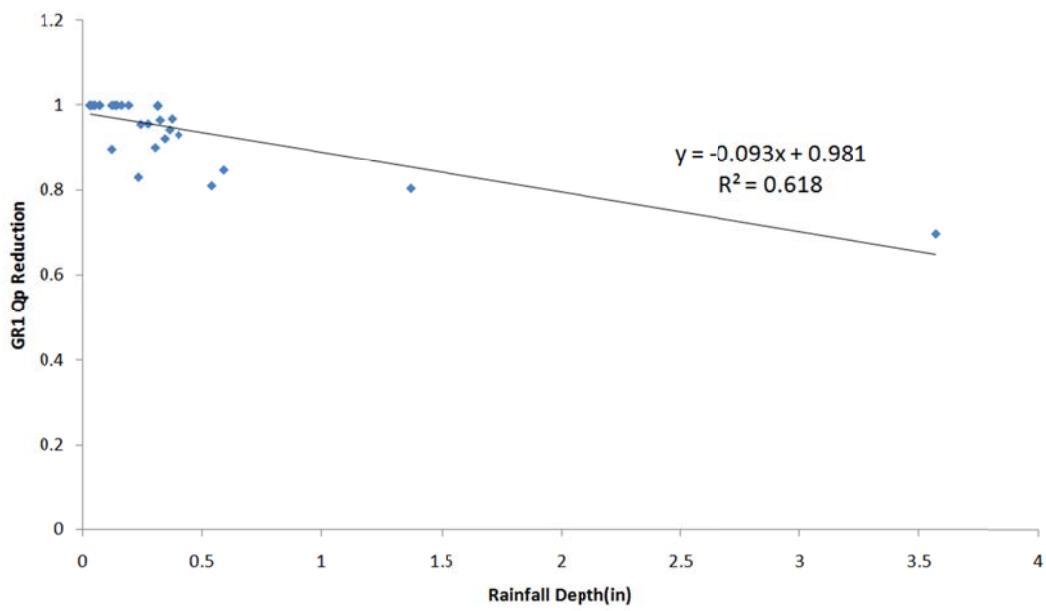

Figure 5.4 Storm depth versus storm runoff volume reduction on Green Roof 1 for all storms observed during 2009-2011 with trend line and linear regression equation

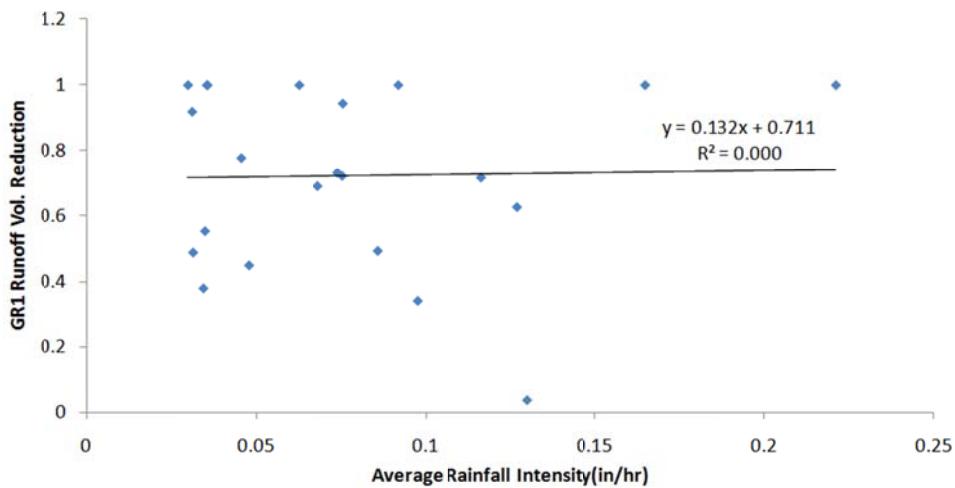

Figure 5.5 Average storm intensity versus storm water runoff peak flow reduction on Green Roof 1 for all storms observed during 2009-2011 with trend line and linear regression equation

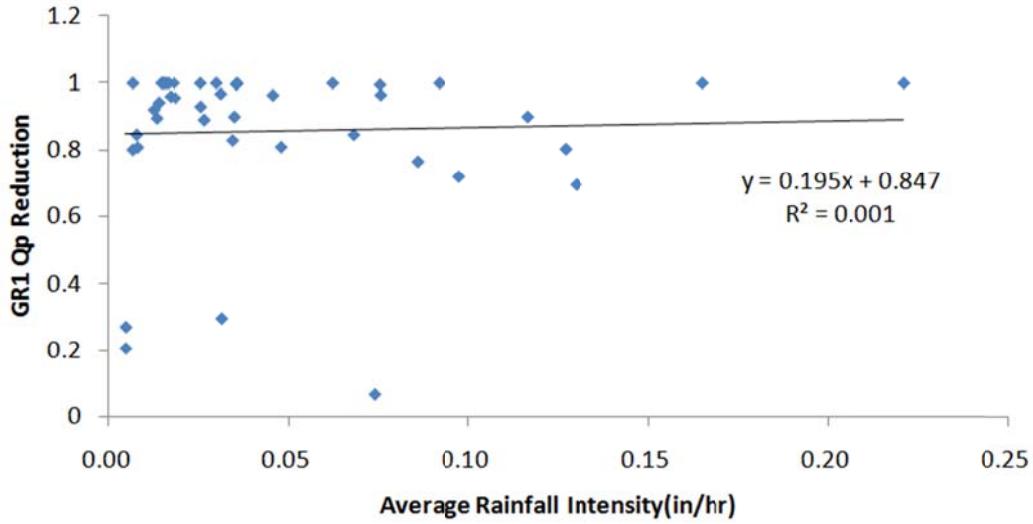

Figure 5.6 Average storm intensity versus storm water runoff peak flow reduction on Green Roof 1 for all storms observed during 2009-2011 with trend line and linear regression equation

5.3.2. Snow

During winter storms, the soil in the green roof may freeze and slowly release the water over an extended period of time, and snow landing on the green roof may accumulate and melt over an extended period. Snow may stay on the roof for several days, or even several weeks (Berghage et al, 2009). It raises difficulties for determining the end date of the snow storm events and runoff discharge flow rate. Furthermore, the rain gauge was not heated and thus was subject to snow accumulation and clogging, making it difficult to determine storm initiation times. So in this report, all the snow storms were not evaluated and the relationship between green roof performance and the snow events wasn't analyzed.

5.3.3. Seasonal Effects

In addition to the effect of rainfall depth, the storm water retention on green roof also depended

on season (Berghage et al, 2009). Water retention in warm months (April through October) was more than in the cool weather months (November through March). In the observed period, limited data were obtained during the summer months (May to August) due to lack of monitoring personnel and equipment failure. As an example of warm weather versus cold weather performance, runoff reduction on Green Roof 1 in April, 2009 was 76% of the 1.1 inches of precipitation, while in February, 2009, runoff was 86% of the 0.27 inch of precipitation on Green Roof 1. In the cool, drier months, less runoff was produced than during the warm, wetter periods. For example, in December, 2009, the runoff reduction was 44% of 2.69 inches of precipitation on Green Roof 1, while 60% of 0.59 inch of precipitation was reduced in October, 2009 on Green Roof 1.

6. Summary and Conclusions

Fifty one Storms were observed and analyzed for the Hamerschlag Hall Green Roof and control roof for the period January 2009 to April 2011. The Green Roof reduced the storm runoff volume, extended the runoff duration time, and decreased the peak flow rate of the runoff compared to the control roof.

The green roof reduced the total amount of the light storm runoff (0.01-0.1 inch) by nearly 100%. The majority of the storms during observed period were of 0.1-0.6 inch, for which the green roof lowered the runoff volume by at least 60%. Data from these 51 storms didn't show a clear relationship between the size of storms and the volume reduction on the green roof due to the

lack of the large storm occurring during the period.

During the storm, precipitation was first absorbed by soil and growing medium and then runoff was generated. It was found that the runoff start was delayed and the runoff duration was extended by the green roof compared to the control roof. The peak flow rate of the runoff from the green roof was reduced by at least 80% for light storms (0.01-0.1 inch), and for moderate storms (0.1-0.6 inch) was reduced by at least 30%.

Appendix B 2010 Storm Summary and Individual Storm Data

Metrics used in Appendix B

Metric	Equation/definition
Vol. Reduction^[a]	$\frac{V_{CR,RUNOFF} - V_{GR,RUNOFF}}{V_{CR,RUNOFF}}$
Relative Duration^[b]	$\frac{D_{GR}}{D_{CR}}$
Duration Extension^[c]	$\frac{D_{GR} - D_{CR}}{D_{CR}}$
Runoff Vol. Ratio^[d]	$\frac{V_{GR,RUNOFF}}{V_{CR,RUNOFF}}$
Q_p^[e]	Obtained from runoff hydrograph
Time to Peak^[f]	(Time of peak runoff rate)-(runoff start time)
Q_p Reduction^[g]	$\frac{Q_{P,CR} - Q_{P,GR}}{Q_{P,CR}}$
Time to Peak Extension^[h]	$\frac{t_{P,GR} - t_{P,CR}}{t_{P,CR}}$
NF^[i]	Sensor not functioning
NA^[k]	Not Applicable

Appendix C 2011 Storm Summary and Individual Storm Data

Metrics used in Appendix C

Metric	Equation/definition
Vol. Reduction^[a]	$\frac{V_{CR,RUNOFF} - V_{GR,RUNOFF}}{V_{CR,RUNOFF}}$
Relative Duration^[b]	$\frac{D_{GR}}{D_{CR}}$
Duration Extension^[c]	$\frac{D_{GR} - D_{CR}}{D_{CR}}$
Runoff Vol. Ratio^[d]	$\frac{V_{GR,RUNOFF}}{V_{CR,RUNOFF}}$
Q_p^[e]	Obtained from runoff hydrograph
Time to Peak^[f]	(Time of peak runoff rate)-(runoff start time)
Q_p Reduction^[g]	$\frac{Q_{P,CR} - Q_{P,GR}}{Q_{P,CR}}$
Time to Peak Extension^[h]	$\frac{t_{P,GR} - t_{P,CR}}{t_{P,CR}}$
NF^[i]	Sensor not functioning
NA^[k]	Not Applicable

Table 2011-7-B Weather Condition for the Storm Event^[i]

Date	Max T(° F)	Min T(° F)	Event
4/25/2011	82	57	Rain

Table 2011-7-C Control Roof and Green Roof Runoff Parameters

Roof	Runoff Start Date	Runoff Start Time	Runoff End Date	Runoff End Time	Runoff Duration(min)
Control	4/25/2011	15:54:00	4/25/2011	18:43:00	169
Green 1	4/25/2011	15:54:00	4/25/2011	18:43:00	169
Green 2	4/25/2011	15:54:00	4/25/2011	18:43:00	169

Table 2011-7-D Rainfall Data from two Measurements Devices

Measurement Type	Depth (in)	Volume(ft ³)
Rain Gauge	0.13	7.04
Control Roof Flume	0.118	6.4

Table 2011-7-E Total Runoff Volume

Roof	Runoff Volume(ft ³)
Control	6.4
Green 1	0
Green 2	0

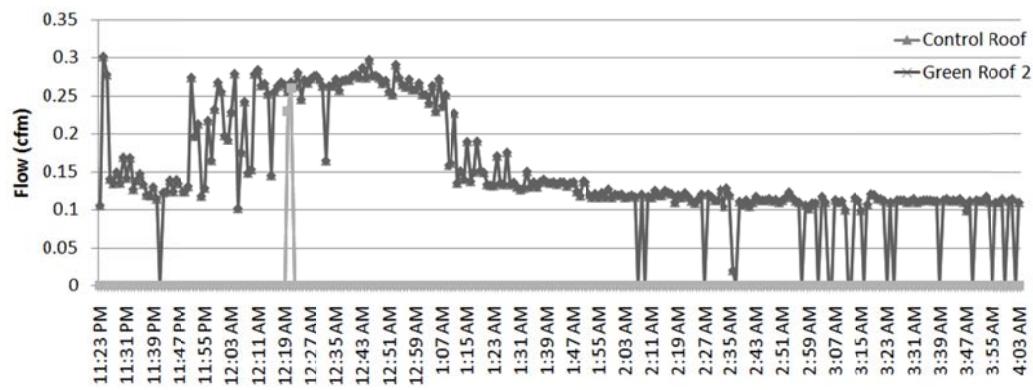

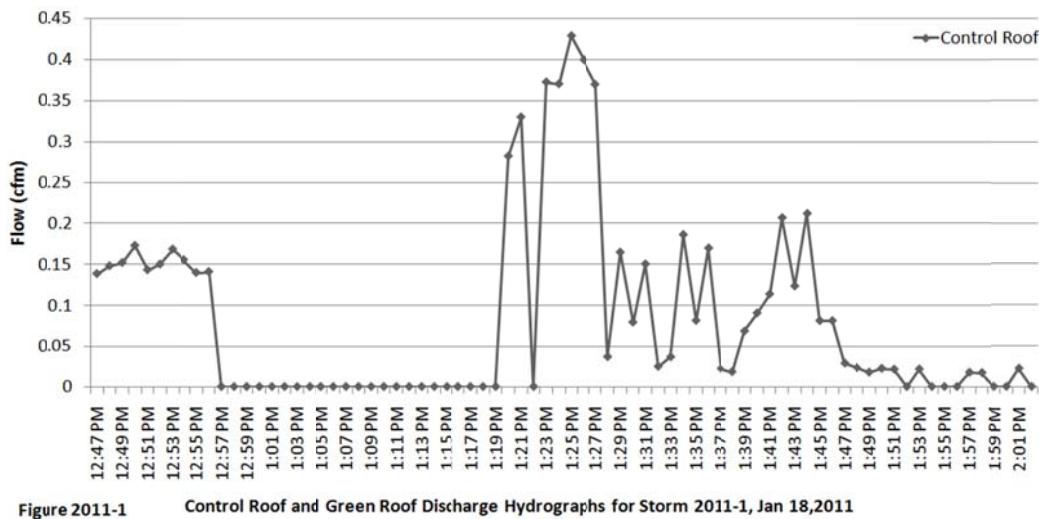

Table 2011-7-F Characteristics of Peak Flows

Roof	Qp ^[e] (cfm)	Time of Peak	Time to Peak ^[f] (min)	Qp Reduction ^[g]	Time to Peak Extension ^[h]
Control	0.46	15:54:00	0	NA ^[k]	NA
Green 1	0	15:54:00	0	1	-1
Green 2	0	15:54:00	0	1	-1

Table 2011-7-G Green Roof Water Retention Characteristics for Storm

Roof	Vol. Reduction ^[a]	Relative Duration ^[b]	Duration Extension ^[c]	Runoff Volume Ratio ^[d]
Green 1	1	0	-1	0
Green 2	1	0	-1	0
